LYGÆINA.

TRAPEZONOTUS DISPAR.

Trapezonotus dispar, Stål, Öfv. Vet. Ak. Förh., 56 (1872); Leth., Hém. Nord., 2 ed. 21 (1874).

Black, with whitish pubescence, on the upper surface scarcely perceptible. *Antennæ* comparatively long, slender, 1st joint, in the ♂, orange. *Rostrum* orange in the ♂. *Pronotum* posteriorly much wider than in front, posterior third (except a spot in the middle, a smaller one towards each posterior angle, and round punctures, which are black), also the side margins throughout, testaceous. *Scutellum* immaculate. *Elytra* as long as the abdomen, testaceous; *clavus* with three to four rows of round black punctures; *corium* with similar but less regularly placed punctures, and at the inner posterior angle a large, rhomboidal black spot; *membrane* fuscous-black; nerves whitish, broad at the base. *Legs*:—♂, *thighs* orange, 2nd and 3rd pairs with a broad ante-apical black ring; *tibiæ*: 1st and 2nd pairs orange, the 2nd black at the base, 3rd black:—♀, *thighs* black, apex orange; *tibiæ*: 1st pair rufous at the base (I have two examples in which all the tibiæ are deep orange, the 2nd and 3rd pairs black at the base); *tarsi* in both sexes black. Length, ♂, 2; ♀, $2\frac{1}{2}$ lines.

I found a few examples on the 17th May last, in an open space among the underwood at Darent Wood, running swiftly in the sunshine.
