

**Largidea marginata** Uhler, MS.

Dark castaneous. Head piceous-black with a rufous spot against the inner margin of the eyes. Second joint of the antennæ sometimes tinged with castaneous. Pronotum rufous; callousities black, the impressed line behind them polished; generally the whole disk behind the callousities is dark castaneous leaving a broad rufous or red margin. Scutellum rufous with a blackish spot on its base. Elytra dark castaneous; the cuneus and sometimes the broad inner margin of the corium rufous. Membrane blackish fuscous; the nervures black. Beneath mostly rufous becoming black on the sternum. Legs nearly black, the femora sometimes rufous beneath.

Described from thirteen examples taken by me on scrub oak at Salida, Colorado, July 24th, 1900. At that time I sent specimens to Dr. Uhler which he determined as *Largidea marginata* Uhler, but the description seems never to have been published.

**Genus Ganocapsus** n. gen.

Body glabrous, oblong, subelongate; head nearly vertical, more elongated than in *Garganus*, clypeus strongly convex, passing the cheeks by one-half its length, vertex distinctly impressed between the inner angles of the eyes. Antennæ long and slender, attenuated toward the apex; first joint thickest, nearly as long as the pronotum; second joint filiform, not at all thickened. Pronotum longer than in *Garganus*, strongly narrowed anteriorly, and the sides distinctly but not deeply sinuated; surface transversely wrinkled, impunctate, collum distinct. Elytra polished, impunctate, strongly shagreened. Rostrum attaining the hind edge of the metasternum. Posterior femora long, terete, scarcely flattened and but little narrowed to the apex; first tarsal joint not longer than the second; arolia large and divaricate as in the allied genera.

This genus is closely allied to *Garganus* but differs in having the second antennal joint filiform, the head more produced with a longer and more convex clypeus, the vertex more distinctly impressed at base, and the pronotum longer with the sides obviously sinuated.

Type *Ganocapsus filiformis* n. sp.

**Ganocapsus filiformis** n. sp.

Form of *Garganus fusiformis*. Color pale sanguineous, elytra black, commissural and costal margins and legs pale yellowish. Length, male 5, female 6 mm.
